

PART 2

Q1: What is the declared width of both boxes?

ANS: Both boxes have a declared width of 300px.

Q2: Which box appears larger in actual size?

ANS: The content-box appears larger because padding and border are added outside the declared width.

Q3: How do padding and border affect the size of the box?

ANS: In content-box, padding and border increase the total size of the box. In border-box, padding and border are included inside the width and height.

Q4: What is the main difference between content-box and border-box?

ANS: content-box keeps width only for content area. border-box includes content, padding, and border inside the given width.

Q5: Why do developers mostly use border-box in real-world projects?

ANS: Developers mostly use border-box because it makes layouts easier to manage and prevents elements from overflowing.

PART 4

Q1: In which experiment did the layout break?

ANS: The layout broke in the content-box experiment.

Q2: In which experiment did the boxes fit properly?

ANS: The boxes fit properly in the border-box experiment.

Q3: What is the reason behind this behavior?

ANS: In content-box, padding and border are added outside the width, so the total size becomes larger than 50%.

In border-box, padding and border are included inside the width, so the layout fits correctly.
